Re: Enabling maintenance & development work on the Enshield admin dashboard

1. What I found

There are **two separate systems** in play, and it's important to keep them distinct:

	Shipping-protection app	Admin dashboard
URL	<code>enshield-shipping-protection.gadget.app (*.gadget.app)</code>	<code>manage.enshield.com/dashboards/main</code>
Purpose	The product/engine — shipping protection installed into Shopify stores	The internal cockpit — Clients, Claims, Errors, Reports
Platform	Gadget (framework v1.5.0), Shopify-connected	Custom build, hosted on a DigitalOcean server (IP 161.35.190.126)
DNS	Managed by Gadget	enshield.com via GoDaddy
Built by	In-house (source available locally)	Insanelab (source not currently in our possession)

Verified facts:

- The dashboard is live at `manage.enshield.com`, resolving to a DigitalOcean server (`161.35.190.126`).
- DNS for `enshield.com` is managed through GoDaddy.
- The dashboard's source code is **not** in our current working repository.

Assumptions still to confirm (asked as questions, not asserted):

- Which framework/stack the dashboard runs on.
- Whether its data syncs from the Gadget/Shopify app or is stored independently.
- Who administers the DigitalOcean server and GoDaddy DNS account.

2. What we need to do the work

To maintain, fix, or extend the dashboard we need:

- 1 **Source code** — repository access + setup notes + confirmed stack.
- 2 **Server access** — SSH/DigitalOcean access and the current deploy method.
- 3 **Database** — connection details and confirmation of the data source.
- 4 **DNS/domain** — confirmation of GoDaddy account control.
- 5 **App logins & config** — admin login(s), `.env/config` values, and third-party API keys.

3. How we'll do it

- 1 **Gather access** (this request) — collect the items above via a secure vault.
- 2 **Audit** — stand up the dashboard in a local/staging environment, map the codebase and its data source, and confirm how (or whether) it connects to the Gadget app.

- 3 **Document** — produce a short architecture + runbook so the two systems are clearly understood and safely deployable.
- 4 **Execute** — carry out the intended fixes/redesign on staging first, then deploy to production once verified.

4. Security note

A portal password was recently shared over plain email. Recommendation: **rotate that password after handover** and move all future credential sharing to a secure vault (1Password / Bitwarden). No credentials should be sent in plain text.
